1. Introduction

The word ‘Grid’ in Grid-computing was chosen by analogy with the electrical network. The idea is that computational resources should be as readily available as electrical energy by simply ‘plugging in to a Grid’. This short article is intended to alert the power system community to the concept of Grid-computing and to initiate a discussion of its potential applications in future power systems. Can the computing ‘Grid’ offer new solutions for the generation, transmission, distribution and power utilisation systems of the future? Some of the questions to be considered are: what is Grid-computing, why is it being developed, and what could it do for power systems?

2. Grid-Computing

Grid-computing has a good pedigree. It is championed by the same people that brought us the World Wide Web, i.e. the particle physics research community. They are introducing this new software technology to fill an immediate and real need (see section 4). Present generation particle-accelerators produce such huge volumes of measurement data, at such high rates, that a new approach is needed to enable the information to be processed, analysed and interpreted by thousands of collaborating scientists throughout the world. To quote from the UK funded GRIDPP web site

The next IT revolution will be the Grid. While the Web is aimed mainly at the exchange of information, the Grid is concerned with the exchange of computer power, data storage, and access to large databases, without users searching for these resources manually. Computer services will become a utility like electricity, supplied via a Grid. Once connected to the Grid, the end user will see it essentially as one large computer system. The Grid is a practical solution to the data-intensive problems that must be overcome if the computing needs of many scientific communities and industry are to be fulfilled over the next decade.

Can future power networks benefit as a spin-off application? In power systems, as a result of the move to renewables, a larger number of smaller generators will call for more active and dynamic operation, especially at distribution level. The future power system will involve many participants: generator owner/operators, generator maintenance providers, generation aggregators, transmission network operators (TNOs), distribution network operators (DNOs), load managers, energy market makers, energy supply companies, metering companies, energy customers, regulators, and governments. Grid-computing could offer an inexpensive and efficient means for participants to compete (but also co-operate) in providing reliable, cheap and sustainable electrical energy supply.

2.1 The nature of Grid-computing

Grid-computing, or ‘the Grid’ for short, uses standard open-source (non-propriety) software to allow a large number of users to share computational resources. In contrast to the limited information sharing provided by the Web, all types of computational

\[1\text{https://www.gridpp.ac.uk/}\]
resources can be shared (i.e. data stores, algorithms and processing power). The sharing of resources is by no means a ‘free-for-all’, however. Access to shared resources is carefully controlled. The computers participating in a Grid create a massive distributed system and the users become part of a ‘virtual organisation’.

2.2 Grid-computing and distributed computing

In the early days of computer networking, various specialised systems enabled file transfer and e-mail within universities and research-led organisations. The introduction of the Web allowed that technology to reach critical mass and develop into the system that we are familiar with today. In a similar way, Grid-computing culminates from earlier developments in ‘distributed computing’ and is widely predicted to be the ‘next big thing’ in computing.

2.3 Grid-computing and the Web

Like the Web, the Grid can operate over the Internet or any other suitable computer networking technology. How does the Grid differ from the Web? Some of the significant differences are show in Table 1.

<table>
<thead>
<tr>
<th>The ‘Web’</th>
<th>The ‘Grid’</th>
</tr>
</thead>
<tbody>
<tr>
<td>low-volume information sharing</td>
<td>high-volume information sharing, distributed computational processes, and computer power sharing</td>
</tr>
<tr>
<td>there is only one Web</td>
<td>there are many separate and distinct Grids</td>
</tr>
<tr>
<td>anyone can ‘join’</td>
<td>a Grid has a carefully controlled set of registered participants</td>
</tr>
<tr>
<td>no intrinsic reliability and security of data transmission</td>
<td>reliable and secure data transmission</td>
</tr>
<tr>
<td>no inherent protection against misuse</td>
<td>certification, authentication, etc. is built in</td>
</tr>
</tbody>
</table>

Table 1: Differences between the ‘Web’ and the ‘Grid’

3. Characteristics and Capabilities

Some of the relevant characteristics and capabilities of Grid-computing are:

- A Grid is created by installing software services, or middleware (e.g. the Globus Toolkit\(^2\)), on a set of networked computers. The middleware provides facilities such as: hardware and software resource location, user authentication, and distributed scheduling of resources and tasks.
- Grid-computing is designed to be scalable (e.g. a Grid should operate equally well with 100,000 participants as with 100).

\(^2\) http://www.globus.org/
• Grid-computing is often regarded as a means for creating inexpensive ‘super-computing’. It is now becoming clear that an equally significant purpose is to enable inexpensive, scalable, reliable and secure distributed computing, usually across corporate boundaries.

4. An Example of a Developing Trans-national GRID Application

The large scale adoption of Grid-computing has been motivated by a number of primarily scientific applications. As an example, and one that we contribute to at Brunel University, we outline briefly the Grid being used by a large scale internationally distributed collaborative experiment in the field of fundamental particle physics. Figure 1 shows the Compact Muon Solenoid Experiment\(^3\), which will operate at the "Large Hadron Collider" for a decade commencing in 2007 will produce stored data at a rate of order 1 Pbyte per year (actual real-time data rate is about 10\(^6\) times higher).

Figure 1  
The Compact Muon Solenoid (CMS) experiment currently under construction. This 12,500 ton particle detector operates at a rate of 40 million beam collisions per second, and will produce stored data at a rate of order 1 Pbyte per year of operation.

\(^3\) http://cmsinfo.cern.ch/Welcome.html/
Figure 2 shows the structure of the GridPP\textsuperscript{4} grid. The physicist (Tier-4 level) will access local (Tier-3) resources, analysis cluster and local storage via a portal device e.g. workstation, laptop or hand-held. Tier-3 are connected to regional Tier-2 centres which are able to service requests, for example, for Monte Carlo production. National Tier-1 centres are repositories for large quantities of data from the experimental sites (located at Tier-0 centres). The hierarchical structure is aimed at minimising bandwidth requirements but the Grid nature allows peer-to-peer communication and direct access to all facilities (broken lines) where authorisation is approved.

The organisation of the implementation of the Grid will take two forms: “clusters” and WorkGroups. In the UK there will be four regional clusters representing Universities and Institutes. These local groupings will collaborate to create regional centres of excellence for Grid activities and build geographically localised regional Tier-2 centres which typically share a single MAN. The WorkGroups, whose remit closely match those within the EU DataGrid\textsuperscript{5}, are delivering the software components of the Grid. Although in some Workgroups there will be a strong regional interest, institutes within a cluster will collaborate with groups in other clusters. Thus the implementation of the Grid conforms to paradigm of “virtual organisations” through the creation of geographically intersecting WorkGroups and clusters which share resources.

Although the Grid outlined above is primarily aimed at providing computational power and distributed data brokerage, plans are also underway to use the Grid for remote monitoring and control of the CMS experimental apparatus itself.

0 centre in Switzerland and in the UK the Tier-1 centre is at CLRC RAL. Geographically distributed Tier 2 centres are located in Scotland, NW England, London and SW England. Brunel University is a member of the “London” Tier 2 centre and is also a local Tier 3 centre in its own right.

5. Potential Benefits for Future Power Systems

Grid-computing could have very significant benefits for almost all the aspects of power systems that involve computers. In the following discussion it is assumed that in the future every electrical generator will be equipped with computational and communication facilities. This does not seem too far-fetched in a world where cars, vending machines, domestic appliances etc. are predicted to be similarly equipped.

5.1 Monitoring and Control

It is anticipated that a large numbers of smaller generators will be introduced in the coming decades, utilising renewable energy and reducing carbon emissions. As these generators are connected into the power system (often embedded at distribution level) it will become necessary to monitor and control their output level and their on/off schedule. The control technology in use at transmission level is not scalable to very large numbers of generators. Grid-computing can provide a relatively inexpensive new technology, allowing the output of embedded generators to be monitored and when necessary controlled.

An outline of a power systems Grid-computing structure is illustrated in Figure 1.

---

**Fig. 1 Outline of a power systems computing Grid**
5.2 Market Entry and Participation

Future electrical energy markets should provide open access to a range of participants from very small organisations (perhaps even individuals) to very large companies. The need to register in the market, receive and transmit financial information, notify the market of technical constraints, etc. can all be provided by Grid-computing. The ability of Grid-enabled systems to interact autonomously will be vital for small generators where manned operation is unlikely to be viable.

5.3 Regulation

A power system computing-Grid would provide regulators with access to complete information on the technical and economic performance of regulated markets. New regulatory rules and incentives could be introduced and disseminated electronically.

5.4 Planning

Planning of future power systems will rely on a collective effort by many companies and agencies. The sharing of accurate, detailed information on the existing system and the ability to use industry-wide computer models and forecasts would facilitate a co-ordinated approach. The creation of a ‘virtual organisation’ including all relevant participants could retrieve some of the benefits of global planning that are often claimed to have been the main advantage of the centralised, vertically-integrated industry that existed before privatisation.

6. Further Development

More than 20 projects are already underway to develop and exploit Grid-computing. The UK research effort includes a £98million initiative, established by the Office of Science and Technology. A National e-Science centre has been created with a number of regional centres⁶. Considerably greater funding has been made available in the EU and the USA. Major computer manufacturers are already seriously committed. However, to our knowledge, there are no projects underway to investigate power system applications. At Brunel University, power system and Grid-computing research teams are collaborating and have obtained funding to underpin research in this area. It is hoped that this field will develop rapidly over the next few years, bringing forward a new technology with significant benefits for the power networks of the future.

7. Conclusions

This short article has introduced the concept of Grid-computing for power systems. It is hoped that further research will lead to the development of specific power network Grid applications. The two references below provide an excellent introduction to Grid-computing technology.
